

# Variables & Data Types

The 4 core types Python uses to store everything — and how to check them.

## 1 — STRINGS (STR)

Text values — always wrapped in quotes.

```
name = "Jordan Avery"
city = "Houston"
print(type(name))
# output:
```

■ Quotes make it a string — even if it looks like a number.

## 2 — NUMBERS (INT & FLOAT)

int = whole numbers · float = decimals.

```
age = 29 # int
score = 94.5 # float
print(age + 1)
# output:
```

■ "29" (quotes) is a string — math on it will error.

## 3 — BOOLEANS (BOOL)

Only two values: True or False. Capital T/F required.

```
active = True
is_done = False
print(type(active))
# output:
```

■ Lowercase true/false is not valid Python — will error.

## 4 — TYPE() & CONVERSION

Check a type with type() · convert with int() float() str().

```
price = "19.99" # str!
price = float(price)
print(price + 1)
# output:
```

■ type() is your debugger — check before you calculate.

## MINI PROJECT — Contact Card Script

Store name, age, phone, and subscription status — each as the correct type.

```
name = "Jordan Avery" age = 29
phone = "555-0148" subscribed = True
print(f"Name: {name} Age: {age} Phone: {phone}")
```
