

# Your First Line of Code

The 4 building blocks in Episode 1 — and how they fit together.

## 1 — PRINT()

Displays output to the screen — the first tool every Python developer uses.

```
print("Hello, World!")
print("Count: " + str(5))
# output:
Hello, World!
Count: 5
```

Tip: When joining text + numbers with +, convert the number with str() first.

## 2 — VARIABLES

Named containers that store a value for later use.

```
name = "Jordan"
age = 29
active = True
print(name, age, active)
# output:
Jordan 29 True
```

Tip: Think of = as 'set this to'. name = 'Jordan' means: name is now Jordan.

## 3 — F-STRINGS

Drop variable values directly into a string using {} curly braces.

```
name = "Jordan"
role = "Analyst"
print(f"Hi, I am {name}.")
print(f"Role: {role}")
# output:
Hi, I am Jordan.
Role: Analyst
```

Tip: Without the f, Python prints {name} as plain text, not the variable's value.

## 4 — STRING MULTIPLICATION

Repeat a string N times with the \* operator.

```
print("-" * 20)
print("=" * 30)
# output:
-----
=====
```

Tip: Works on any string — great for borders, dividers, and report headers.

## MINI PROJECT — Personal Intro Card Generator

Combine all 4 concepts: variables, f-strings, print(), and string multiplication.

```
name = "Jordan Avery"
role = "Project Coordinator"
experience = "3 years"
print("=" * 60)
print(f"  Name: {name} | {role} | {experience}")
print("=" * 60)
# output:
=====
  Name: Jordan Avery | Project Coordinator | 3 years
=====
```

## NEXT — EP02: Variables & Data Types

str · int · float · bool · type() · conversion — and the mistake that trips up almost everyone.
