

Your First Line of Code

The 4 building blocks in Episode 1 — and how they fit together.

1 — PRINT()

Displays output on screen.

```
print("Hello, World!")
print("Count: " + str(5))
# output:
Hello, World!
```

■ print() accepts any data type — wrap numbers in str() first.

2 — VARIABLES

Named containers that store a value for later use.

```
name = "Jordan"
age = 29
active = True
print(name, age)
```

■ = means assign, not 'equals'. Right side is stored into left.

3 — F-STRINGS

Drop variables directly into a string using {} curly braces.

```
name = "Jordan"
role = "Analyst"
print(f"Hi, I am {name}.")
print(f"Role: {role}")
```

■ The f before the quote is required — without it, {name} prints literally.

4 — STRING MULTIPLICATION

Repeat a string N times with the * operator.

```
print("-" * 20)
print("=" * 30)
# output:
-----
```

■ Works on any string — great for borders, dividers, and formatting.

MINI PROJECT

— Personal Intro Card Generator

Combine all 4 concepts into a formatted terminal card.

```
name = "Jordan Avery"
role = "Project Coordinator"
experience = "3 years"
print("=" * 40)
print(f"  Name: {name} | {role} | {experience}")
```
